Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

The procedures used to develop this document and those intended for its further maintenance are described in the ISO/IEC Directives, Part 1. In particular the different approval criteria needed for the different types of ISO documents should be noted. This document was drafted in accordance with the editorial rules of the ISO/IEC Directives, Part 2 (see www.iso.org/directives).

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights. Details of any patent rights identified during the development of the document will be in the Introduction and/or on the ISO list of patent declarations received (see www.iso.org/patents).

Any trade name used in this document is information given for the convenience of users and does not constitute an endorsement.

For an explanation on the meaning of ISO specific terms and expressions related to conformity assessment, as well as information about ISO's adherence to the WTO principles in the Technical Barriers to Trade (TBT) see the following URL: Foreword - Supplementary information

The committee responsible for this document is ISO/TC 156, *Corrosion of metals and alloys*, Working Group 13, *High Temperature Corrosion*.

Introduction

In contrast to high temperature corrosion occurring in gaseous environment covered in ISO 21608 and ISO 13573, this International Standard focuses on high temperature corrosion occurring on materials that are in direct contact with molten corrosive substances or solid corrosive substances.

The present document considers the case of a metallic material covered with a corrosive deposit that itself can remain in the solid state or melt during the high temperature exposure.

The closely-related condition involving exposure in a compacted powder is described in ISO 17248:—¹⁾ and that involving immersion in a molten salt or other liquid in ISO 17245:—¹⁾.

1) To be published.

Corrosion of metals and alloys — Test method for high temperature corrosion testing of metallic materials by application of a deposit of salt, ash, or other substances

1 Scope

This International Standard specifies the method for high temperature corrosion testing of metallic materials by applying a deposit of salt, ash, and/or other substances and exposing them to high temperature in a controlled gas environment to evaluate their corrosion resistance. The deposit is applied prior to high temperature exposure by spraying, dipping, or painting.

This International Standard does not cover methods where test pieces are fully or partially embedded in corrosive substances or immersed in liquids. These methods are covered in ISO 17248:—²⁾ and ISO 17245:—²⁾, respectively.

2 Normative references

The following documents, in whole or in part, are normatively referenced in this document and are indispensable for its application. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

3 Terms and definitions

For the purposes of this document, the terms and definitions given in ISO 8044 and the following apply.

3.1

affected layer

layer beneath the test piece surface that is affected in its composition and/or structure due to corrosion

2) To be published.

**3.2
corrosive deposit**

mixture made up of salt, ash, and/or other substances that contains compounds that are expected to react with the metal at high temperature

Note 1 to entry: The corrosive deposit can be molten at test temperature.

**3.3
controlled gas environment**

flowing gas mixture of defined composition and flow rate which affects the behaviour of the corrosive deposit

**3.4
descaling**

removal of corrosion products and corrosive phases from the test piece surface before measurement of the mass of the remaining metal

4 Test method

4.1 Principle

The test shall be performed with at least two test pieces of each material to ensure reproducibility of the test results. These test pieces can be used for determination of mass change, dimensional changes, and/or for observation of the surface and/or cross section.

4.2 Reagents and materials

4.2.1 Test pieces

The test pieces shall have the form of a rectangular plate, a disc, or a cylinder with a minimum surface area of 300 mm² and a minimum thickness of 1,5 mm .

If the test pieces cannot be made according to these specifications, the shape and dimensions of the test pieces shall be in accordance with the agreement between the parties involved.

The test pieces shall be machined to remove the strata affected by cutting.

The final finishing of the surface of the test pieces shall be performed with abrasives with mean particle diameter of approximately 15 µm. This can be achieved by the use of abrasives, according to [Table 1](#).

Table 1 — Designation and mean diameter of particles of coated abrasives according to regional standards

Standard	Designation	Mean diameter µm	Region
FEPA ^a 43-1984 R 1993: Grit sizes for coated abrasives ISO 6344 Coated abrasives - Grain size analysis	P1200	15,3 ± 1,0	Europe
JIS R6001-87	#1000	15,5 ± 1,0	Japan
ANSI B74.12-92 — Specifications for the size of abrasive grain – grinding wheels, polishing, and general industrial uses	600	16,0	America
^a Federation of European producers of abrasives.			

If another surface finish is required by the parties involved, the surface finish condition shall be described.

Sharp edges of test pieces might give anomalous behaviour. These shall be slightly rounded during the final stages of test piece preparation.

The dimensions of the test pieces shall be measured prior to exposure at a minimum of three positions for each dimension with a precision of $\pm 0,02$ mm by means of the measuring instruments specified in ISO 3611 and ISO 6906.

After ultrasonically degreasing in isopropanol or ethanol, the test pieces shall be dried in hot air or in a desiccator.

If it is suspected that test pieces might absorb significant amounts of atmospheric contaminants such as water, it is recommended that the cleaned test pieces are stored in a desiccator prior to weighing and exposure.

The mass of the test pieces shall be determined prior to exposure. At least two measurements shall be made for each test piece. The difference between the measurements shall not exceed 0,05 mg.

4.2.2 Corrosive deposit

The type of deposit to be used in the test shall be selected in accordance with the environment for which the test is intended. It shall be prepared either by taking ash from actual equipment or by mixing chemicals of reagent grade.

The melting temperature of the deposit should be measured in advance.

The deposit load applied will depend upon the chemistry of the deposit. Typical levels employed may range from 1 mg/cm^2 for sprayed salt deposits to 30 mg/cm^2 for suspended ash deposits.

The deposit can be applied as a solution, as a suspension, or as a dry powder. As a solution the deposit may be sprayed onto the test piece. If this technique is used it is recommended that the test piece be heated, e.g. by a hot plate.

For a suspension the corrosive deposit shall be ground in a mortar. It shall then be suspended in a liquid that does not react with the deposit or substrate. The suspension shall be mixed well. The deposit can be applied for instance by dipping or painting.

A specified amount shall be applied on the surfaces of interest. Drying is recommended prior to exposure.

4.3 Test apparatus

4.3.1 Design of apparatus

The apparatus shall be composed, as a whole, of the temperature regulating device for heating all test pieces at a uniform temperature. The heating device shall be equipped with a testing portion capable of separating the test pieces from outside air. The gas supply shall be controlled by a gas flow meter.

A basic design of a closed, horizontal, apparatus is shown in [Figure 1](#). A design of the complete furnace setup is shown in Figure 1 of ISO 21608.

- Key**
- 1 test gas inlet
 - 2 test chamber
 - 3 heating unit
 - 4 test piece support
 - 5 test piece
 - 6 thermocouple
 - 7 gas exit

Figure 1 — Apparatus using a horizontal furnace

The test chamber shall not be composed of materials that react significantly with the gas environment or the corrosive substance during the test. If the reaction is not avoidable, the reaction shall be small enough to neglect a change in composition of the atmosphere.

4.3.2 Temperature monitoring

The temperature distribution of the furnace shall be characterized at the exposure temperature prior to the testing to determine the width of the isothermal zone by the use of a movable thermocouple.

The temperature regulating device shall be capable to guarantee that the temperature of the test piece is kept within the permissible range given in [Table 2](#).

Table 2 — Permissible tolerance of temperature of test pieces

Temperature range, °C	≤300	300 to 600	600 to 800	800 to 1 000	1 000 to 1 200	>1 200
Temperature tolerance, °C	±2	±3	±4	±5	±7	By agreement

Thermocouple sheaths shall be used to protect the thermocouple wires. The thermocouple sheaths shall fully withstand the test temperature and environment.

A specimen thermocouple shall be positioned as close as possible to the test piece. If the experimental condition does not allow the use of such a thermocouple, the temperature of the test piece has to be deduced from the furnace calibration using dummy test pieces in an appropriate environment.

Calibration of thermocouples shall be performed in accordance with ASTM E220, ASTM E230, and ASTM E1350. A representative thermocouple taken from the batch of wire can be calibrated.

Thermocouples shall be recalibrated annually or at the beginning and the end of each experiment if there is uncertainty about thermocouple stability.

4.3.3 Gas supply

The gas supply system shall be capable of supplying the test gases at a constant flow rate to the test piece chamber described in [4.3.1](#).

When a humidifying regulator is used, it shall be capable of adjusting to the desired humidity. Deionized water of electrical conductivity less than $1 \mu\text{S cm}^{-1}$ shall be used.

The gas line between humidifying regulator and test chamber shall be kept above the dew point in order to avoid condensation.

The gas flow shall be monitored by a gas flow meter. The flow meter shall be located as close as possible to the inlet of the test chamber except where a humidifying regulator is used, in which case, it shall be located upstream from the humidifier.

In the case that the gas is humidified, the water vapour content shall be measured. This can be achieved by, e.g. the use of a hygrometer before the test chamber or by measuring the amount of water after condensation of the exhaust gases or by measuring the water consumption of the humidifier over the course of the experiment.

4.4 Procedure

4.4.1 Preparation and placement of the test piece

The support shall be inert to the environment (e.g. alumina).

The configuration of the test piece on a support is shown in [Figure 2](#).

Supports shall be baked in air to remove volatile compounds before their first use. The recommended baking conditions are at least 24 h at a temperature of $1\ 000\text{ }^{\circ}\text{C}$. If water absorption is suspected to have occurred, used crucibles shall be dried at significantly above $100\text{ }^{\circ}\text{C}$.

In case of melting deposits, the test pieces shall be placed horizontally.

Key

- 1 test piece
- 2 inert support

Figure 2 — Test pieces on an inert support

If different materials are tested simultaneously within one furnace and if significant evaporation of the materials is expected, the test pieces shall be placed within separate horizontally oriented tubes (e.g. alumina) stacked onto each other in order to minimize cross contamination. To ensure sufficient

gas mixing, the specimen-containing tubes shall be placed at least 30 cm from the gas inlet. [Figure 3](#) illustrates this setup.

Key

- 1 test chamber
- 2 horizontally oriented tubes
- 3 test gas inlet
- 4 gas exit
- 5 test pieces

Figure 3 — Position of horizontal tubes as seen as a cross section from the inlet of the tube furnace (a) and in a longitudinal section of the tube furnace (b)

4.4.2 Test environment

The composition of the test gas shall be chosen in a way that it keeps the corrosive activity of the corrosive deposit stable.

The flow rate of the test gas shall be sufficient as to fill the test chamber at least three times an hour. This is to ensure that the corrosion rate is not determined by the supply of the reactants.

If equilibrium in the gas phase is required, the gas flow shall be preheated, and/or an appropriate catalyst shall be used, if necessary.

4.4.3 Heating method

The test pieces in their crucibles shall be placed in the furnace either at room temperature or at the test temperature, by agreement between the parties. In the former case, the time to reach the test temperature shall be recorded.

Where test pieces are loaded into a cold furnace, heating shall be carried out in the test gas. In the case of humidified atmospheres, the humidification shall not be started until the temperature in the coldest part of the test chamber exceeds the dew point of possible condensing phases.

If heating in the test gas is not acceptable from a safety perspective, heating shall be performed in a gas similar in composition to the test gas but with the critical components absent until a temperature has been reached at which point, the safety concerns have been resolved. Where test pieces are loaded into a hot furnace, a flow of inert gas can be used during the loading procedure.

The heating shall be carried out in a manner that the temperature of test pieces does not exceed the upper limit of permissible temperatures listed in [Table 2](#).

4.4.4 Test duration

The test is defined to commence when the test piece temperature exceeds 97 % of the desired test temperature, T_{dwell} (measured in K).

The test ends when the temperature of the test piece falls below 97 % of the desired test temperature, T_{dwell} (measured in K), or when the test piece is removed from the hot furnace.

The test duration shall be relevant to the intended application and agreed upon between the parties concerned. The materials behaviour, observed in short-term exposures, might not continue at long durations. Therefore, for testing of relevance to long-term service conditions, the entire exposure time shall be at least 300 h.

4.4.5 Cooling of test pieces

If furnace cooling is used, it shall be carried out in the test gas down to 200 °C and the time to cool down to 50 °C shall be recorded. The test pieces can also be removed from the furnace at test temperature. A dry purge gas atmosphere shall be applied for a sufficient duration before removing the test pieces from the furnace. In the case of humidified atmospheres, the humidification shall be stopped before the temperature in the coldest part of the test chamber falls below 200 °C.

If cooling in the test gas is not acceptable from a safety perspective, cooling shall be performed in a gas similar in composition to the test gas but with the critical components absent.

4.4.6 Discontinuous testing

For discontinuous exposure, the same heating methods (4.4.3) and cooling methods (4.4.5) shall be applied each time the test pieces are reloaded for continued exposure.

If the consumption rate of the reactive species in the deposit is unknown, then the corrosive deposit shall be replaced each time before the test pieces are reloaded.

4.5 Determination of mass change

4.5.1 Principle

One method to determine corrosion kinetics is to measure mass change. This is recommended only for test pieces fully coated with the corrosive deposit, and only if the corrosive deposit can be removed completely after testing. Duplicate test pieces of each material shall be used. Test pieces should be weighed as soon as possible or shall be stored in a desiccator after removal from the furnace until immediately before weighing. When handling test pieces, tweezers shall be used. Test pieces shall never be touched with the hands to avoid contamination (e.g. grease, salts). Care has to be taken when using gloves as the contamination with the separating agent of the gloves leads to falsification in mass determination. If repeated measurements are not consistent, the temperature and humidity of the weighing environment has to be controlled.

4.5.2 Measurements prior to testing

The mass of the test pieces shall be determined prior to exposure [$m_T(t_0)$, Figure 5 in ISO 21608]. At least two individual measurements shall be made for each test piece with a precision of 0,02 mg. The maximum difference between the measurements shall not exceed $\pm 0,05$ mg.

4.5.3 Descaling prior to mass determination

If descaling prior to mass determination is intended, all corrosion products shall be removed from test pieces with a minimum removal of sound metal. This shall be done according to ISO 8407.

Additional procedures are given in [Annex A](#) (see [Table A.1](#) and [Table A.2](#)).

After descaling, the test pieces shall not be used for further corrosion testing.

NOTE These procedures are not suitable to remove internal corrosion products, as defined in ISO 26146.

4.5.4 Measurement of corrosion mass loss

The mass loss of the test pieces due to corrosion shall be determined according to ISO 8407.

5 Examination of surface and microstructure of corroded test pieces

Metallographic examination shall be made of the surface and cross section. Detailed procedures for examinations are provided in ISO 26146.

6 Report

6.1 Matters to be described

The following data, where known, shall be included in the report on the test results.

6.1.1 Test material

- a) Manufacturer
- b) Name of material (manufacturer designation; ASTM, DIN, etc.)
- c) Grade or symbol
- d) Heat number / Batch number
- e) Chemical composition (analysis technique)
- f) Processing condition
- g) Heat treatment condition
- h) Microstructure of the material determined according to ASTM E3 and etching according to ASTM E407

6.1.2 Test piece

- a) Designation of test piece
- b) Sampling conditions of the test piece from raw material (crystallographic orientation, rolling direction, etc.)
- c) Dimensions (in mm) and surface area, A , (in cm²) of test piece
- d) Surface finish condition of test piece
- e) Degreasing method of test piece
- f) Method of test piece support
- g) Initial mass

6.1.3 Testing environments

- a) Test temperature
- b) Characteristic heating and cooling curves of the test piece

- c) Test duration
- d) Volume of test chamber
- e) Composition of test gas, including humidity
- f) Volumetric flow rate of test gas in normal cubic meters per second
- g) Chemical composition, particle size distribution (if available), and origin of the corrosive deposit
- h) Characteristics of the corrosive deposit determined by differential thermal analysis (DTA), differential scanning calorimetry (DSC) and thermogravimetric analysis (TGA), if available
- i) Amount of corrosive deposit used per coated surface area
- j) Size, type, and material of the support used

6.1.4 Test results

- a) Mass loss caused by descaling procedures, according to [4.5.3](#).
- b) Mass loss caused by the corrosion experiment, according to [4.5.4](#).
- c) In case of determination of corrosion kinetics: mass loss, Δm , divided by surface area, A , as a function of time.
- d) Image of appearance after testing.
- e) Image of cross section including the surface layer of the metallographic section of test piece after testing. The chosen magnifications must clearly show the extent of the total attack in a single micrograph.
- f) Results of any metallographic investigations performed, according to [Clause 5](#).
- g) Results of analysis of corrosive deposit after long-term exposure, if performed according to [4.2.2](#).

6.1.5 Supplementary note

It is desirable to additionally describe the following matters in the report on the test results:

- a) mechanical properties of the initial material;
- b) microstructure of the initial material and sampling conditions;
- c) further details of the test apparatus.

Annex A (informative)

Chemical and electrolytic procedures for removal of corrosion products

A.1 General

In the development of this International Standard, a number of sources were consulted to identify chemical and electrolytic descaling procedures. They can be used in addition to those listed in ISO 8407 and they are specifically designed for the purpose of the tests described in this International Standard. This Annex summarizes the results of the survey.

Prior to adopting these procedures, the user should conduct a test on control samples to ensure the efficiency of the chosen method. Excess descaling might result in dissolution not only of corrosion products but also of metal substrates.

A.2 Procedures

[Table A.1](#) and [Table A.2](#) summarize various chemical and electrolytic procedures for removal of corrosion products. The specific choice of procedure for a given material will depend on many factors, including previous experience.

For all the procedures listed, it is recommended that the surfaces should be maintained vertical during cleaning. This will minimize retention of any gases released during the procedure.

The times specified represent recommendations appropriate for mass-loss studies in the context of Figure 1 in ISO 8407:2009.

When using electrolytic procedures, selecting adequate electrolysis parameters and using blank test pieces is recommended, in order to ensure precise removal of corrosion products. A typical setup is shown in [Figure A.1](#).

WARNING — When working with dangerous substances (such as sodium hydroxide, potassium permanganate, hydrochloric acid), all necessary safety precautions shall be taken.

Table A.1 — Chemical procedures for removal of corrosion products

Designation	Material	Chemical agents	Total time	Temperature	Remarks
C.7.10	Heat-resistant stainless steels and superalloys	Step 1: 180 g of sodium hydroxide (NaOH) 30 g of potassium permanganate (KMnO ₄) Distilled water to make 1 000 ml	30 min to 40 min	boiling	Repetition of step 1 / step-2 / washing is effective for sticky corrosion products
		Step 2: 100 g of ammonium citrate ((NH ₄) ₂ C ₆ H ₆ O ₇) Distilled water to make 1 000 ml	30 min to 40 min	boiling	Brushing by soft brush in the middle of treatment is effective
C.3.4	Carbon steels and low-alloy steels	50 ml of hydrochloric acid (HCl, $\zeta = 1,19$ g/ml) 0,5 g of hexamethylenetetramine or of 1,3-di- <i>n</i> -butyl-2-thiourea Distilled water to make 1 000 ml	30 min to 40 min	60 °C	Repetition of acid cleaning / washing is effective for sticky corrosion products

Table A.2 — Electrolytic procedures for removal of corrosion products

Designation	Material	Chemical agents	Total time	Temperature	Remarks
E.5.1	Heat-resistant stainless steels and superalloys	Molten salt containing mass fractions of 40 % of sodium hydroxide (NaOH) and 60 % of sodium carbonate (Na ₂ CO ₃)	2 min to 5 min	500 °C to 650 °C	Current density of 0,3 to 1,0 A/cm ² Repetition of electrolysis and washing is effective for sticky scale Brushing by soft brush in the middle of washing is effective Optimization of electrolysis is important
